Aim of the paper

Explore the impact of emotion reappraisal messaging on betrayal aversion (a decision-making preference that occurs when people avoid situations involving trust to avoid disutility associated with the negative emotions experienced when being betrayed) related to vaccination decision and on related vaccine hesitancy

Why is it important?

- Proportion of population remains vaccine hesitant
- Betrayal aversion recently discovered as an important factor in vaccination decision
- Health communication strategies necessary to foster vaccine confidence
- Role of emotion one relevant aspect of communication strategies
- Emotion reappraisal is aimed at restructuring the meaning and impact of an emotion eliciting situation

< D > < A >

Context on vaccine hesitancy

- Vaccines are a cost-effective public health intervention which can prevent disease outbreak and lower the disease burden
- Delay in acceptance or refusal of a vaccine, has typically been explained by the 3C model, which articulates three factors- confidence, convenience, and complacency that determine vaccine acceptance (Larson H. J., 2014), (MacDonald, 2015)
- Other factors associated with vaccine hesitancy acceptance like include demographic factors, individual risk attitudes and perception of responsibility, trust in authorities involved with in vaccination drives, lack of information and/or vaccine misinformation (Truong, 2022)

Image: A math a math

Context on betrayal aversion

- While selecting amongst products related to safety (such as airbags or vaccines) individuals who are betrayal averse might tend to take up less efficient protection to stave off a comparatively small chances of getting hurt by a safety device itself
- Individuals have shown significantly higher probability of buying safety devices like smoke alarms and airbags, and marginally higher probability of getting vaccinated when the risks associated with these safety products involved no chance of betrayal
- Betrayal aversion is sensitive to the characteristics of the betrayal in question, such as whether an aligned or unaligned political party or scientists were connected to vaccines (Alsharawy et al., 2022)

・ロト ・ 日 ・ ・ ヨ ・

Context on health communication strategies

- Health communications which address emotions in addition to providing information would be an effective strategy (Ferrer & Ellis, 2019) (Chou, 2020)
- Messaging targeting emotional engagement has been effective in the context of health behaviors, such as improved rates of cancer screening and detection (Perugini & Bagozzi, 2001), (Dillard & Nabi, 2006), (Lang & Yegiyan, 2008).
- Studies have reported higher willingness to become vaccinated in the presence of effective communication [(Quinn, et al., 2013), (Nyhan, Reifler, Richey, and Freed, 2014), (Odone, et al., 2015), (Milkman, et al., 2021)]
- Emotion regulation has previously been used to reduce, strengthen, or maintain the positive or negative emotions as required (Gross J. J., 2014) and has been found to have positive effect on psychological health and well-being and in achieving goals (Aldao, 2015)

• Literature on health communication strategies targeting emotions

- Dillard, J. P., and Nabi R. L. 2006. "The persuasive influence of emotion in cancer prevention and detection messages." Journal of Communication, 56(suppl1) : S123–S139.
- Literature on betrayal aversion
 - Koehler, J., and Gershoff A. 2003. "Betrayal Aversion: When Agents of Protection Become Agents of Harm." Organizational Behavior and Human Decision Processes, 90.
 - Alsharawy, A., Dwibedi, E., Aimone, J., and Ball, S. 2022. "Vaccine Hesitancy and Betrayal Aversion." Annals of Biomedical Engineering, 50(7): 794–804.
- Literature on emotion reappraisal
 - Gross, J., and John. O. 2003. "Individual differences in two emotion regulation processes: Implications for affect, relationships, and well-being." Journal of Personality and Social Psychology, 85: 348–362.

- Online survey using Qualtrics via Amazon Mechanical Turk (MTurk)
- Inclusion criteria for the MTurk responders- United States resident with 97% and higher HIT (Human Intelligence Tasks) approval rating and at least 5000 HITs approved in MTurk
- Participants received \$2.5 as compensation
- Final sample includes 1189 participants
- Vignette experiment on hypothetical scenario about a novel future disease described as both highly infectious and deadly, with an available free and easy-to-take vaccine (via a pill)
- Within-subject design to detect betrayal aversion to vaccines
- Between-subjects design to detect effect of reappraisal messaging conditions on betrayal aversion and vaccine hesitancy

イロト イロト イヨト イヨ

Statement displayed uniformly across 4 messaging treatments (including *Neutral, Ambiguous, Negative and Positive* emotion reappraisal messaging conditions)

"Health is very personal, so people often have emotional reactions associated with medical procedures. Sometimes, people do not make their best decisions when they are feeling emotional; that is why it's good to plan ahead. For the medical decision here, (*...). Register today to get the vaccine at an opportune time."

For example, for the Ambiguous reappraisal messaging condition, the statement displayed is:

"Health is very personal, so people often have emotional reactions associated with medical procedures. Sometimes, people do not make their best decisions when they are feeling emotional; that is why it's good to plan ahead. For the medical decision here, really focus on using your emotions to help you make a good decision. Register today to get the vaccine at an opportune time."

・ロト ・ 一ト・ ・ ヨト・

Table: Variation in Messaging Conditions Displayed Statements

SI.No.	Message	Statement Displayed
	Treatment	
1	Neutral	(*adopt a neutral attitude by thinking objectively and analytically rather than in an emotional way)
2	Ambiguous	(*really focus on using your emotions to help you make a good decision)
3	Negative	(*really focus on the emotions associated with how bad you would feel if you experienced the negative ef- fects of getting the disease if you chose to not get vac- cinated)
4	Positive	(*really focus on the emotions associated with how good you would feel if you experienced the positive ef- fects of receiving the additional protection against the disease if you chose to get vaccinated)

For the Betrayal aversion messaging condition, the statement displayed is:

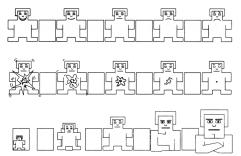

"Health is very personal, so people often have emotional reactions associated with medical procedures. Specifically, negative emotions associated with a fear of the procedure itself causing harm is known as 'betrayal aversion'. While this response can be helpful for avoiding certain dangerous situations, we do not want betrayal aversion to prevent us from receiving safe and effective protection against the virus. For the medical decision here, try to avoid letting any feelings of betrayal aversion prevent you from getting your vaccine. Register today to get the vaccine at an opportune time." Hypothetical disease scenario

- Unvaccinated face a 2% risk of death
- Divided Risk: Vaccinated face a 1.01% risk of death, where 1% was due to the virus, while the explanation for the remaining 0.01% varies across treatments
 - $\bullet\,$ Non-Betrayal treatment: the 0.01% described as "problems unrelated to the vaccine"
 - Active Betrayal treatment: the 0.01% described as "vaccine-induced complications (side effects)"
- Undivided Risk: Vaccinated face a 1.01% risk of death due to contracting the virus

Methodology

Additional Survey Components

 Self Assessment Manikin (SAM) tool- Participants asked to self-report their emotions the domains of pleasure, arousal, and dominance at the beginning and at the end of the experiment

• Questions on vaccine attitude and experience (Vaccine history, Global Vaccine Confidence Index, PACV, Covid vaccine history), emotion regulation (ERQ), demographic characteristics (gender, age, ethnicity, race, education, and political orientation)

Variables of interest

- Willingness to become vaccinated measured by single 7-point Likert question with response alternatives ranging from "Definitely reject" at 1 to "Definitely accept" at 7 under both betrayal scenarios
- The difference between an individual's willingness to get vaccinated in the Active Betrayal treatments and their willingness to get vaccinated in the Non-Betrayal treatment gives us the measure of betrayal aversion at the individual level

Table: List of Divided Risk Treatment Conditions

Treatment (Explanations for the 1.01% chance of Death after Vaccine)						
Message Treatment	Betrayal aversion question 1/	Participants				
	Betrayal aversion question 2

Standard errors (clostered at the region level) are in parentheses. Likert-tcale (7-point) measures, including dependent vaniable, are tandardized at the individual level (z-score). A more positive score on PACV or VCI denotes higher hestancy. *** $p < \Delta t$, *** $p < \Delta t$, ***

Figure: Willingness to get the vaccine disassociated by motivation, across reappraisal messaging treatments, controlling for VCI (average of four z-scored measures)

- Emotion reappraisal messages were successful in targeting individuals' betrayal aversion
- Messages that appealed to embrace the ambiguity in the emotions felt regarding vaccination decisions as well as messages that appealed to embracing the positive emotions from getting vaccinated were both successful in decreasing betrayal aversion
- Heterogeneous effect of education (High school or less compared to more education) on betrayal aversion and vaccine hesitancy
- Heterogeneous effect of political orientation (democrats vs. republicans or independents) on betrayal aversion

- Use of reappraisal messaging in targeted healthcare messaging related to emotion reappraisal
- Channels through which betrayal aversion affects vaccine hesitancy
- Further field research on messaging that influences betrayal aversion
