Heavy-tailed asymptotics and simulation are used to

- approximate the probability of extreme events,
- gain understanding of the underlying mechanism that is most likely to lead to extreme events. For example,
  - cumulative build-up,
  - shocks transferred through a system,
  - passage through bottleneck states,
  - etc...

Heavy-tailed asymptotics and simulation are used to

### The Regular Variation Framework

We consider a regular variation framework where  $\{X_n\}$  is a sequence of random variables,  $A_n$  a sequence of events, and the probabilities  $\{p_n\}$  where

$$p_n = \mathbb{P}\{X_n \in A_n\},\$$

form a regularly varying sequence; for any  $\lambda > 0$ ,

$$\lim_{n\to\infty}\frac{p_{[\lambda n]}}{p_n}=\lambda^{-\alpha},$$

< 口 > < (型 >

for some  $\alpha \geq 0$  called the *index of regular variation*.

The One Big Jump Heuristic

## The One Big Jump Heuristic

- Let  $\{Z_k\}$  be independent and identically distributed (iid) random variables.
- Suppose  $\mathbb{P}{Z_1 > n}$  is regularly varying.
- Then, for each fixed  $k \ge 1$ ,

$$\mathbb{P}\{Z_1 + \cdots + Z_k > n\} \sim k\mathbb{P}\{Z_1 > n\}, \text{ as } n \to \infty.$$

Notation:  $a_n \sim b_n$  if  $a_n/b_n \rightarrow 1$ .

0000
000
000

Applying the Heavy-Tailed Heuristics 000 000 00000

#### The One Big Jump Heuristic

### Proof

- Suppose for simplicity that  $Z_1 \ge 0$ .
- Lower bound (inclusion/exclusion):

$$\mathbb{P}\{S_k > n\} \ge \mathbb{P}\{\bigcup_{k=1}^n Z_k > n\} \ge k\mathbb{P}\{Z_1 > n\} - k(k-1)\mathbb{P}\{Z_1 > n\}^2.$$

**Upper bound:** (k = 2),  $\epsilon > 0$  arbitrary,

$$\begin{split} \mathbb{P}\{S_2 > n\} &= 2\mathbb{P}\{Z_1 + Z_2 > n, Z_2 \leq \epsilon n\} \\ &+ \mathbb{P}\{Z_1 + Z_2 > n, Z_1 > \epsilon n, Z_2 > \epsilon n\} \\ &\leq 2\mathbb{P}\{Z_1 > (1 - \epsilon)n\} + \mathbb{P}\{Z_1 > n\epsilon\}^2 \\ &\sim 2(1 - \epsilon)^{-\alpha}\mathbb{P}\{Z_1 > n\}. \end{split}$$

Henrik Hult

The One Big Jump Heuristic

## The One Big Jump Heuristic

A General Version

- Let  $\{Z_k\}$  be independent and identically distributed (iid) random variables.
- Suppose  $\mathbb{P}{Z_1 > n}$  is regularly varying and put  $S_n = Z_1 + \cdots + Z_n$ .
- Then, there is uniform convergence:

$$\lim_{n\to\infty}\sup_{x\geq\lambda_n}\left|\frac{\mathbb{P}\{S_n>x\}}{n\mathbb{P}\{Z_1>x\}}-1\right|=0,$$

for  $\lambda_n \to \infty$  sufficiently fast.<sup>1</sup> Ex:  $(\alpha > 2)$ :  $\lambda_n = a\sqrt{n \log n}$ ,  $a > \sqrt{\alpha - 2}$ ,  $(\alpha = 2)$ :  $\lambda_n / \sqrt{n^{1+\gamma}} \to \infty$ ,  $\gamma > 0$ ,  $(\alpha < 2)$ :  $S_n / \lambda_n \to 0$ , in probability.

<sup>1</sup>These conditions are called the Nagaev conditions. General conditions under supexponentiality are given in [3].

	The Heavy-Tailed Heuristics ○○○○ ○○● ○○○	Applying the Heavy-Tailed Heuristics 000 000 0000 0000
The Heaviest Tail Wins		
Proof		

Suppose for simplicity that Z and Y are non-negative. For arbitrary  $\epsilon \in (0, 1)$ ,

$$\mathbb{P}\{Z + Y > n\} = \mathbb{P}\{Z + Y > n, Z > (1 - \epsilon)n\} + \mathbb{P}\{Z + Y > n, Z \le (1 - \epsilon)n\}$$
  
 $\leq \mathbb{P}\{Z > (1 - \epsilon)n\} + \mathbb{P}\{Y > \epsilon n\}$   
 $= \mathbb{P}\{Z > (1 - \epsilon)n\} + o(\mathbb{P}\{Z > \epsilon n)\})$   
 $\sim (1 - \epsilon)^{-\alpha} \mathbb{P}\{Z > n\}.$ 

The reverse inequality is trivial when Y is non-negative.

Applying the Heavy-Tailed Heuristics

Random Sums

## Random Sums

- Let  $\{Z_k\}$  be iid with  $\mathbb{P}\{Z_1 > n\}$  regularly varying with index  $-\alpha$ .
- Let *N* be the random number of terms (*N* has sufficiently light tails, e.x. exponential), independent of  $\{Z_k\}$ .
- Determine the asymptotic decay of  $\mathbb{P}{S_N > n}$ , where  $S_N = \sum_{k=1}^N Z_k$ .

Applying the Heavy-Tailed Heuristics

Random Sums

## Random Sums

Heuristic: Think of *N* as "not very large". Then,  $S_N = \sum_{k=1}^N Z_k$  is large, most likely because precisely one of the  $Z_k$ 's is large, so expect

$$\mathbb{P}\{S_N > n\} \sim \text{const } \mathbb{P}\{Z_1 > n\}.$$

What is the constant?

By conditioning on *N*:

$$\mathbb{P}\{S_N > n\} = \sum_{k=1}^{\infty} \mathbb{P}\{N = k\}\mathbb{P}\{Z_1 + \dots + Z_k > n\}$$
$$\sim \sum_{k=1}^{\infty} \mathbb{P}\{N = k\}\mathbb{R}\{Z_1 > n\}$$
$$= \mathbb{E}[N]\mathbb{P}\{Z_1 > n\}.$$

See e.g. [7] for more details.

Infinitely Divisible Random Variables

## Infinitely Divisible Laws

• X has an infinitely divisible law if, for each *n*, there are iid random variables  $Y_{1,n}, \ldots, Y_{n,n}$  such that

$$X\stackrel{\scriptscriptstyle d}{=} Y_{1,n}+\cdots+Y_{n,n}.$$

The Lévy-Itô decomposition states that X can be represented in law as a sum of three independent parts

$$X \stackrel{\text{\tiny d}}{=} \mu + \sum_{k=1}^{N} Z_k + \text{ small jumps } + \text{ Gaussian.}$$

where  $Z_k \ge 1$  is distributed according to  $\nu(\cdot)/\nu(1,\infty)$ ,  $\nu$  is the Lévy measure, and *N* has a Poisson distribution with mean  $\nu(1,\infty)$ .

Applying the Heavy-Tailed Heuristics

Infinitely Divisible Random Variables

## Infinitely Divisible Laws

 Suppose ν(n,∞) is regularly varying with index −α, so P{Z<sub>1</sub> > n} is regularly varying with index −α.

 Then

$$X \stackrel{\text{d}}{=} \mu + \sum_{k=1}^{N} Z_k + \underbrace{\text{small jumps}}_{\text{light tails}} + \underbrace{\text{Gaussian.}}_{\text{light tails}}$$

**The random sum**  $\sum_{k=1}^{N} Z_k$  satisfies

$$\mathbb{P}\Big\{\sum_{k=1}^{N} Z_k > n\Big\} \sim E[N] \mathbb{P}\{Z_1 > n\} = \nu(1,\infty) \frac{\nu(n,\infty)}{\nu(1,\infty)} = \nu(n,\infty).$$

The heaviest tail wins argument implies that

$$\mathbb{P}\{X > n\} \sim \nu(n,\infty).$$

The reverse implication also holds, even under subexponentiality, see [4].

The Heavy-Tailed Heuristics 0000 000 000 Applying the Heavy-Tailed Heuristics

Stochastic Integrals

## Stochastic Integrals

Decomposing the Lévy process as

the stochastic integral becomes

the **heaviest tail wins** argument tells us that  $\sum_{k=1}^{N_t} Y_{\tau_k} \Delta X_{\tau_k}$  is the most important term (if it has heavy tails).

KTH Royal Institute of Technology

▲□▶ ▲圖▶ ▲厘▶ ▲厘

Asymptotics and Simulation of Heavy-Tailed Processes

Applying the Heavy-Tailed Heuristics

Stochastic Integrals

## Stochastic Integrals Studying $\sum_{k=1}^{N_t} Y_{\tau_k} \Delta X_{\tau_k}$

Each term  $Y_{\tau_k} \Delta X_{\tau_k}$  is a product of independent rv's so **Breiman's Lemma** implies that each term satisfies

$$\mathbb{P}\{Y_{\tau_k}\Delta X_{\tau_k} > n\} \sim E[Y_{\tau_k}^{\alpha}]\mathbb{P}\{\Delta X_{\tau_k} > n\}.$$

The terms  $Y_{\tau_k} \Delta X_{\tau_k}$ , k = 1, 2, ... are not independent, but the **one big jump heuristic** tells us that, most likely, only one  $\Delta X_{\tau_k}$  is large, so one expects that

$$\mathbb{P}\{\int_{0}^{1} Y_{t} dX_{t} > n\} \sim \mathbb{P}\{\sum_{k=1}^{N_{1}} Y_{\tau_{k}} \Delta X_{\tau_{k}} > n\} \sim E[N_{1}]\mathbb{P}\{Y_{\tau} \Delta X_{\tau} > n\} \\ \sim E[Y_{\tau}^{\alpha}]E[N_{1}]\mathbb{P}\{\Delta X_{\tau} > n\} = E[Y_{\tau}^{\alpha}]\nu(n,\infty),$$

where  $\tau$  is the time of the big jump.
