Summary : We revisit the problem of mutually unbiased measurements in the context of estimating the unknown state of a d -level quantum system, first studied by W. K. Wootters and B. D. Fields [7] in 1989 and later investigated by S. Bandyopadhyay et al [3] in 2001 and A. O. Pittenger and M. H. Rubin [6] in 2003. Our approach is based directly on the Weyl operators in the L^2 -space over a finite field when $d = p^r$ is the power of a prime. When d is not a prime power we sacrifice a bit of optimality and construct a recovery operator for reconstructing the unknown state from the probabilities of elementary events in different measurements.

Key words : Mutually unbiased measurements, finite field, Weyl operators, error basis.

AMS 2000 Mathematics Subject Classification 47L90, 47N50, 81P68 (?)

1 Introduction

This is almost an expository account of a well-known problem of quantum probability and statistics arising in the context of quantum information theory. There is a d -level quantum system whose pure states are described by unit vectors in a d -dimensional complex Hilbert space \mathcal{H} equipped with the scalar product $\langle \varphi | \psi \rangle$ between elements φ, ψ in \mathcal{H} . This scalar product is linear in the variable ψ and antilinear in the variable φ . Throughout this exposition we assume that d is finite. Denote by $\mathcal{B}(\mathcal{H})$ the \star -algebra of all operators on \mathcal{H} . The complex d^2 -dimensional vector space $\mathcal{B}(\mathcal{H})$ will also be viewed as a Hilbert space with the scalar product $\langle X | Y \rangle = \text{Tr} X^\dagger Y$ where X^\dagger denotes the adjoint of the operator X . Denote by $\mathcal{S}(\mathcal{H}) \subset \mathcal{B}(\mathcal{H})$ the compact convex set of all nonnegative (definite) operators of unit trace. Any element ρ in $\mathcal{S}(\mathcal{H})$ is called a *state* of the system. The extreme points of $\mathcal{S}(\mathcal{H})$ are precisely one dimensional orthogonal projections. They are called *pure states*. In the Dirac notation any pure state can be expressed as $|\psi\rangle\langle\psi|$ where ψ is a unit vector in \mathcal{H} . Denote by $\mathcal{P}(\mathcal{H})$ the set of all orthogonal

projection operators (or, simply, projections) on \mathcal{H} . Any element P in $\mathcal{P}(\mathcal{H})$ is called an *event* concerning the system and the quantity $\text{Tr}\rho P$ is interpreted as the probability of the event P in the state ρ . In the context of quantum information theory the state of a quantum system can be utilized as an information resource. If the system is in an unknown state ρ it is important to estimate ρ from “independent repeated measurements”. If we choose and fix an orthonormal basis $\{e_0, e_1, \dots, e_{d-1}\}$ in \mathcal{H} then ρ is described in this basis by a nonnegative definite matrix $((\rho_{ij}))$ where $\rho_{ij} = \langle e_i | \rho | e_j \rangle$.

Thus determination of ρ involves the determination of $d^2 - 1$ real parameters, namely, $\rho_{ii}, i = 1, 2, \dots, d - 1, \text{Re}\rho_{ij}, \text{Im}\rho_{ij}, 0 \leq i < j \leq d - 1$. (Note that $\rho_{00} = 1 - \sum_{i=1}^{d-1} \rho_{ii}$ and $\rho_{ij} = \bar{\rho}_{ji}$.)

By an *elementary measurement* $\mathcal{M} = \{P_0, P_1, \dots, P_{d-1}\}$ we mean a family of d mutually orthogonal one dimensional projection operators $P_j, j = 0, 1, 2, \dots, d - 1$ so that $\sum_0^{d-1} P_j = I$, the identity operator. If the measurement \mathcal{M} is performed when the state of the system is ρ , the result of such a measurement is one of the classical outcomes $j \in \{0, 1, 2, \dots, d - 1\}$ with probability $\text{Tr}\rho P_j = p_j$ for each j . Independent repeated trials of the measurement in the same state ρ yield frequencies f_j for each elementary outcome j and f_j can be viewed as an estimate of p_j for each j . Thus an elementary measurement covers at most $d - 1$ degrees of freedom concerning ρ in view of the relation $\sum_{j=0}^{d-1} p_j = 1$. In order to estimate ρ it is therefore necessary to examine the frequencies of elementary outcomes in at least $d + 1$ elementary measurements $\mathcal{M}_j, 0 \leq j \leq d$ where no two of the measurements \mathcal{M}_i and \mathcal{M}_j have any “overlap of information”. Such an attempt is likely to cover all $(d + 1)(d - 1) = d^2 - 1$ degrees of freedom involved in reconstructing or estimating the unknown ρ . To bring clarity to the notion of “nonoverlap of information” in a pair of elementary measurements it is useful to look at the \star -abelian algebra

$$\mathcal{A}(\mathcal{M}) = \left\{ \sum_{j=0}^{d-1} a_j P_j \mid a_j \in \mathbb{C}, j = 0, 1, \dots, d - 1 \right\}.$$

Any element $X = \sum_{j=0}^{d-1} x_j P_j$ in $\mathcal{A}(\mathcal{M})$ can be looked upon as a complex-valued observable where P_j is interpreted as the event that “ X assumes the value x_j ”. Of course, this is justified if all the x_j 's are distinct scalars. If x is any scalar then the event that X assumes the value x is the projection $\sum_{j: x_j=x} P_j$. Thus the subalgebra $\mathbb{C}I \subset \mathcal{A}(\mathcal{M})$ consists precisely of constant-valued observables. Such an interpretation motivates the following formal definition.

Definition 1.1 Two elementary measurements $\mathcal{M} = \{P_0, P_1, \dots, P_{d-1}\}$, $\mathcal{M}' = \{Q_0, Q_1, \dots, Q_{d-1}\}$ are said to be *weakly mutually unbiased* (WMUB) if

$$\mathcal{A}(\mathcal{M}) \cap \mathcal{A}(\mathcal{M}') = \mathbb{C}I,$$

and *strongly mutually unbiased* (SMUB) if, in the Hilbert space $\mathcal{B}(\mathcal{H})$, the subspaces $\mathcal{A}(\mathcal{M}) \ominus \mathbb{C}I$ and $\mathcal{A}(\mathcal{M}') \ominus \mathbb{C}I$ are mutually orthogonal. (Here, for two subspaces $S_1 \subset S_2 \subset \mathcal{B}(\mathcal{H})$, $S_2 \ominus S_1$ denotes the orthogonal complement of S_1 in S_2).

Clearly SMUB implies WMUB. We shall now describe these two properties in terms of the quantities $\text{Tr}P_iQ_j$.

Proposition 1.2 Two elementary measurements $\mathcal{M} = \{P_0, P_1, \dots, P_{d-1}\}$, $\mathcal{M}' = \{Q_0, Q_1, \dots, Q_{d-1}\}$ are SMUB if and only if

$$\text{Tr}P_iQ_j = d^{-1} \text{ for all } i, j, \in \{0, 1, 2, \dots, d-1\}. \quad (1.1)$$

Proof: Note that the subspaces $\mathcal{A}(\mathcal{M}) \ominus \mathbb{C}I$ and $\mathcal{A}(\mathcal{M}') \ominus \mathbb{C}I$ are respectively spanned by the subsets $\{P_j - d^{-1}I, 0 \leq j \leq d-1\}$ and $\{Q_j - d^{-1}I, 0 \leq j \leq d-1\}$. Thus the orthogonality of these two subspaces is equivalent to the condition

$$0 = \langle P_i - d^{-1}I | Q_j - d^{-1}I \rangle = \text{Tr}(P_i - d^{-1}I)(Q_j - d^{-1}I) = (\text{Tr}P_iQ_j) - d^{-1}$$

for all i, j in $\{0, 1, 2, \dots, d-1\}$. \square

Proposition 1.3 Let $\mathcal{M} = \{P_0, P_1, \dots, P_{d-1}\}$, $\mathcal{M}' = \{Q_0, Q_1, \dots, Q_{d-1}\}$ be two elementary measurements. Suppose

$$L = [\text{Tr}(P_i - P_0)(Q_j - Q_0)], \quad i, j \in \{1, 2, \dots, d-1\}$$

and J_{d-1} is the $(d-1) \times (d-1)$ matrix all the entries of which are unity. Then \mathcal{M} and \mathcal{M}' are WMUB if and only if

$$\det \left(I_{d-1} + J_{d-1} + d^{-1}LJ_{d-1}L^\dagger - LL^\dagger \right) > 0. \quad (1.2)$$

Proof: Let $X \in \mathcal{A}(\mathcal{M}) \cap \mathcal{A}(\mathcal{M}')$. Then there exist scalars a_i, b_j , $i, j \in \{1, 2, \dots, d-1\}$ such that

$$\begin{aligned} X &= d^{-1}(\text{Tr}X)I + \sum_{i=1}^{d-1} a_i(P_i - P_0) \\ &= d^{-1}(\text{Tr}X)I + \sum_{j=1}^{d-1} b_j(Q_j - Q_0). \end{aligned}$$

Thus \mathcal{M} and \mathcal{M}' are WMUB if and only if the set $\{P_1 - P_0, P_2 - P_0, \dots, P_{d-1} - P_0, Q_1 - Q_0, Q_2 - Q_0, \dots, Q_{d-1} - Q_0\}$ of $2(d-1)$ elements in the Hilbert space $\mathcal{B}(\mathcal{H})$ is linearly independent. This, in turn, is equivalent to the strict positive definiteness of the partitioned matrix

$$\left[\begin{array}{c|c} [\text{Tr}(P_i - P_0)(P_j - P_0)] & [\text{Tr}(P_i - P_0)(Q_j - Q_0)] \\ \hline [\text{Tr}(Q_i - Q_0)(P_j - P_0)] & [\text{Tr}(Q_i - Q_0)(Q_j - Q_0)] \end{array} \right], \quad i, j \in \{1, 2, \dots, d-1\}$$

of order $2(d-1)$. We have

$$\mathrm{Tr}(P_i - P_0)(P_j - P_0) = \mathrm{Tr}(Q_i - Q_0)(Q_j - Q_0) = \begin{cases} 2 & \text{if } i = j, \\ 1 & \text{if } i \neq j. \end{cases}$$

Thus, \mathcal{M} and \mathcal{M}' are WMUB if and only if

$$\left[\begin{array}{c|c} I_{d-1} + J_{d-1} & L \\ \hline L^\dagger & I_{d-1} + J_{d-1} \end{array} \right]$$

has a strictly positive determinant. Left multiplication of this matrix by the matrix

$$\left[\begin{array}{c|c} I_{d-1} & -L(I_{d-1} + J_{d-1})^{-1} \\ \hline 0 & I_{d-1} \end{array} \right]$$

with unit determinant yields the equivalent condition

$$\det \left(I_{d-1} + J_{d-1} - L(I_{d-1} + J_{d-1})^{-1}L^\dagger \right) > 0. \quad (1.3)$$

Since

$$(I_{d-1} + J_{d-1})^{-1} = I_{d-1} - d^{-1}J_{d-1},$$

condition (1.3) reduces to condition (1.2). \square

Corollary 1.4 If the matrix L of Proposition 1.3 satisfies the inequality $\|L\| < 1$ (where $\|\cdot\|$ is the standard operator norm in the \star -algebra $\mathcal{B}(\mathbb{C}^{d-1})$) then \mathcal{M} , \mathcal{M}' are WMUB. Furthermore \mathcal{M} , \mathcal{M}' are SMUB if and only if $L = 0$.

Proof: Immediate. \square

In the context of minimizing the number of elementary measurements required for estimating the state ρ of a quantum system Proposition 1.2 emphasizes the importance of the search for $d+1$ elementary measurements which are pairwise SMUB. When d is a prime power p^r the existence of such a family of SMUB measurements was proved by Wootters and Fields [7]. Alternative proofs of this result were given by S. Bandyopadhyay et al in [3] and Pittenger and Rubin in [6]. In this paper we shall present a proof of the same result by using the commutation relations of Weyl operators in the L^2 space of the finite field \mathbb{F}_{p^r} . When $d = p_1^{m_1} p_2^{m_2} \dots p_n^{m_n}$ with p_i 's being prime we shall use the Weyl commutation relations in the L^2 space of the additive abelian group $\otimes_{i=1}^n \mathbb{F}_{p_i^{m_i}}$ and study the problem of estimating the unknown state of a d -level system. This leads to an interesting reconstruction formula for a state ρ in terms of probabilities of $d^2 - 1$ events arising from $\prod_{i=1}^n (p_i^{m_i} + 1)$ elementary measurements. However, one would like to express ρ in terms of the probabilities of elementary outcomes in $(\prod_{i=1}^n p_i^{m_i} + 1)$ elementary measurements.

2 The case $d = p^r$

Let $\dim \mathcal{H} = d = p^r$ be a prime power. For any prime power q denote by \mathbb{F}_q the unique (upto a field isomorphism) finite field of cardinality q . Choose and fix any nontrivial character χ of the additive group \mathbb{F}_d and put

$$\langle x, y \rangle = \chi(xy), \quad x, y \in \mathbb{F}_d. \quad (2.1)$$

One can, for example, look upon \mathbb{F}_d as an r -dimensional vector space over \mathbb{F}_p , express any element x in \mathbb{F}_d as an ordered r -tuple: $x = (s_1, s_2, \dots, s_r)$ where $0 \leq s_i \leq p - 1$ for each i and put

$$\chi(x) = \exp \frac{2\pi i}{p} s_1. \quad (2.2)$$

Then we have $|\langle x, y \rangle| = 1$, $\langle x, y \rangle = \langle y, x \rangle$, $\langle x, y_1 + y_2 \rangle = \langle x, y_1 \rangle \langle x, y_2 \rangle$ and $\langle x, 0 \rangle = 1$ for all y in \mathbb{F}_d . In other words, $\langle \cdot, \cdot \rangle$ is a nondegenerate symmetric bicharacter for \mathbb{F}_d . Identify the Hilbert space \mathcal{H} with $L^2(\mathbb{F}_d)$, using the counting measure in \mathbb{F}_d , and put

$$|x \rangle = 1_{\{x\}}, \quad x \in \mathbb{F}_d$$

where $1_{\{x\}}$ is the indicator function of the singleton subset $\{x\}$ in \mathbb{F}_d . Then $\{|x \rangle, x \in \mathbb{F}_d\}$ is an orthonormal basis for \mathcal{H} labelled by the elements of \mathbb{F}_d . Now, consider the unique unitary operators U_a, V_b in \mathcal{H} determined by the relations

$$\begin{aligned} U_a |x \rangle &= |a + x \rangle, \\ V_b |x \rangle &= \langle b, x \rangle |x \rangle \quad \text{for all } x \in \mathbb{F}_d. \end{aligned}$$

Then we have

$$U_a U_b = U_{a+b}, \quad V_a V_b = V_{a+b}, \quad (2.3)$$

$$V_b U_a = \langle a, b \rangle U_a V_b. \quad (2.4)$$

Elementary algebra shows that

$$\text{Tr} (U_{a_1} V_{b_1})^\dagger U_{a_2} V_{b_2} = d \delta_{a_1, a_2} \delta_{b_1, b_2} \quad (2.5)$$

for all a_1, a_2, b_1, b_2 in \mathbb{F}_d . In particular, the family $\{U_a V_b, a, b \in \mathbb{F}_d\}$ of d^2 unitary operators constitute an orthogonal basis for the Hilbert space $\mathcal{B}(\mathcal{H})$. This is an example of a unitary error basis in the theory of error correcting quantum codes [4]. Notice also the fact that $\{U_a\}$ and $\{V_b\}$ are like the position and momentum representations obeying the Weyl commutation relations in classical quantum mechanics. In view of this property we call any operator of the form $\lambda U_a V_b$, $|\lambda| = 1$, $a, b \in \mathbb{F}_d$ a *Weyl operator*. We say that (2.3) and (2.4) constitute the *Weyl commutation relations*. The usefulness of such an error basis of Weyl operators in the study of quantum codes has been explored in [1], [2],[5]. We shall slightly modify the error basis $\{U_a V_b\}$ by multiplying each element $U_a V_b$ by an appropriate phase factor. Once again

viewing \mathbb{F}_d as an r -dimensional vector space over \mathbb{F}_p , expressing any $x \in \mathbb{F}_d$ as an ordered r -tuple $x = (s_1, s_2, \dots, s_r)$ with $0 \leq s_i \leq p-1$ for each i and considering the basis elements $e_i = (0, 0, \dots, 0, 1, 0, \dots, 0)$ of the field \mathbb{F}_d with 1 in the i -th position and 0 elsewhere we write $x = s_1 e_1 + s_2 e_2 + \dots + s_r e_r$ and define

$$\alpha(a, x) = \chi \left(a \left\{ \sum_{i < j} s_i s_j e_i e_j + \sum_j \frac{s_j(s_j - 1)}{2} e_j^2 \right\} \right), a_j x \in \mathbb{F}_d \quad (2.6)$$

where χ is the character chosen and fixed at the beginning of this section.

Now put $\bar{\mathbb{F}}_d = \mathbb{F}_d \cup \{\infty\}$ and write

$$W(a, x) = \begin{cases} \alpha(a, x) U_x V_{ax} & \text{if } a \in \mathbb{F}_d, x \in \mathbb{F}_d, \\ V_x & \text{if } a = \infty. \end{cases} \quad (2.7)$$

Then we have the following proposition.

Proposition 2.1 The family $\{I, W(a, x), a \in \bar{\mathbb{F}}_d, x \in \mathbb{F}_d \setminus \{0\}\}$ is an orthogonal basis of unitary operators for the operator Hilbert space $\mathcal{B}(\mathcal{H})$ satisfying the relations

$$W(a, x)W(a, y) = W(a, x + y) \text{ for all } a \in \bar{\mathbb{F}}_d, x \in \mathbb{F}_d. \quad (2.8)$$

Proof : The first part is immediate from the fact that the family of operators under consideration differs from the family $\{U_x V_y, x, y \in \mathbb{F}_d\}$ only by a scalar factor of modulus unity in each element. If $a \in \mathbb{F}_d, x = \sum s_i e_i, y = \sum t_i e_i$ we have from (2.3) (2.4)

$$\begin{aligned} W(a, x)W(a, y) &= \alpha(a, x)\alpha(a, y)\langle ax, y \rangle U_{x+y} V_{a(x+y)} \\ &= \alpha(a, x)\alpha(a, y)\overline{\alpha(a, x+y)}\langle ax, y \rangle W(a, x+y) \end{aligned}$$

where the coefficient of $W(a, x+y)$ is of the form $\chi(az)$ with

$$\begin{aligned} z &= \sum_{i < j} s_i s_j e_i e_j + \sum_j \frac{s_j(s_j - 1)}{2} e_j^2 + \sum_{i < j} t_i t_j e_i e_j + \sum_j \frac{t_j(t_j - 1)}{2} e_j^2 \\ &\quad - \sum_{i < j} (s_i + t_i)(s_j + t_j) e_i e_j - \sum_j \frac{(s_j + t_j)(s_j + t_j - 1)}{2} e_j^2 + \sum_{i, j} s_i t_j e_i e_j \\ &= 0. \end{aligned}$$

This proves (2.8) when $a \in \mathbb{F}_d$. When $a = \infty$, (2.8) is a part of (2.3). \square

Theorem 2.2 There exists a family of one dimensional orthogonal projection operators $\{P(a, x), a \in \bar{\mathbb{F}}_d, x \in \mathbb{F}_d\}$ satisfying the following :

$$(i) \quad W(a, x) = \sum_{y \in \mathbb{F}_d} \langle x, y \rangle P(a, y)$$

- (ii) $P(a, y) = d^{-1} \sum_{x \in \mathbb{F}_d} \overline{\langle x, y \rangle} W(a, x),$
- (iii) $P(a, x)P(a, y) = \delta_{x,y}P(a, x),$
- (iv) $\sum_{x \in \mathbb{F}_d} P(a, x) = I,$
- (v) $\text{Tr } P(a, x)P(b, y) = d^{-1}$ for all $a \neq b; a, b \in \bar{\mathbb{F}}_d; x, y \in \mathbb{F}_d.$

Proof : By Proposition 2.1 the correspondence $x \rightarrow W(a, x)$ is a unitary representation of the additive abelian group \mathbb{F}_d and $\{\langle \cdot, y \rangle, y \in \mathbb{F}_d\}$ is the set of all its characters. Thus the decomposition of $\{W(a, \cdot)\}$ into its irreducible components yields a spectral measure $P(a, \cdot)$ on \mathbb{F}_d satisfying (i), (iii) and (iv). Substituting from (i) the expression for $W(a, x)$ in the right hand side of (ii) and using the orthogonality relations for characters we get (ii). Taking trace on both the sides of (ii) and observing that $W(a, 0) = I$ and $\text{Tr } W(a, x) = 0$ for $x \neq 0$ we get $\text{Tr } P(a, y) = 1$. Thus each $P(a, y)$ is a one dimensional projection. Substituting for $P(a, x)$ and $P(a, y)$ from (ii) in the left hand side of (v) we have from (2.7), (2.3) and (2.4)

$$\begin{aligned}
& \text{Tr } P(a, x)P(b, y) \\
&= d^{-2} \sum_{z_1, z_2 \in \mathbb{F}_d} \langle x, z_1 \rangle \langle y, z_2 \rangle \text{Tr } W(a, z_1)W(b, z_2) \\
&= d^{-2} \sum_{z_1, z_2 \in \mathbb{F}_d} \langle x, z_1 \rangle \langle y, z_2 \rangle \alpha(a, z_1) \alpha(b, z_2) \langle az_1, z_2 \rangle \text{Tr } U_{z_1+z_2} V_{az_1+bz_2}.
\end{aligned}$$

Now observe that the (z_1, z_2) -th term of the sum on the right hand side is nonzero only if $z_1 + z_2 = 0, az_1 + bz_2 = 0$. If $a \neq b$ this is possible only if $z_1 = z_2 = 0$. This proves (v). \square

Corollary 2.3 Let $\mathcal{M}_a = \{P(a, x), x \in \mathbb{F}_d\}$. Then $\{\mathcal{M}_a, a \in \bar{\mathbb{F}}_d\}$ is a set of $(d+1)$ elementary measurements which are pairwise SMUB.

Proof: Immediate from Propostion 1.2. \square

Our next result yields a recovery formula for any state ρ from the probability distributions $\{\text{Tr } \rho P(a, x), x \in \mathbb{F}_d\}$ on \mathbb{F}_d arising from the measurements $\{\mathcal{M}_a, a \in \bar{\mathbb{F}}_d\}$.

Theorem 2.4 Let $\{P(a, x), a \in \bar{\mathbb{F}}_d, x \in \mathbb{F}_d\}$ be the projections in Theorem 2.2. Then, for any state ρ on $L^2(\mathbb{F}_d)$ the following holds:

- (i) $\rho = \sum_{a \in \bar{\mathbb{F}}_d} \sum_{z \in \mathbb{F}_d} \{\text{Tr } \rho P(a, z) - \frac{1}{d+1}\} P(a, z)$
- (ii) $\rho = \sum_{\substack{x, y \in \mathbb{F}_d \\ a \in \bar{\mathbb{F}}_d}} \overline{\langle x, y \rangle} \{\text{Tr } \rho P(a, y)\} W(a, x)$

Proof: From the first part of Proposition 2.1, it follows that ρ admits the expansion

$$\rho = d^{-1} \left\{ I + \sum_{\substack{a \in \bar{\mathbb{F}}_d \\ x \in \mathbb{F}_d \setminus \{0\}}} \left[\text{Tr } \rho W(a, x)^\dagger \right] W(a, x) \right\}$$

in terms of the orthogonal basis arising from the Weyl operators. Now substitute in the right hand side the expressions for $W(a, x)$ in (i) of Theorem 2.2 and use the orthogonality relations for characters:

$$\sum_{x \in \mathbb{F}_d} \overline{\langle x, y \rangle} \langle x, z \rangle = d \delta_{y, z}$$

Then we obtain the identity (i) of the theorem. If we substitute for $P(a, z)$ from the identity (ii) of Theorem 2.2 we obtain the second identity of the theorem. \square

Remark: If we make repeated independent measurements \mathcal{M}_a , obtain the frequencies for the different events $P(a, z)$ and substitute those frequencies for the different probabilities $\text{Tr} \rho P(a, z)$ in the unknown state ρ we will get an unbiased and asymptotically consistent estimate $\hat{\rho}$ of ρ but $\hat{\rho}$ may not be a positive operator. One may replace $\hat{\rho}$ by the normalised version of the positive part or the modulus of $\hat{\rho}$ at the cost of losing unbiasedness. This also increases the computational cost.

3 Estimation of states in the general case

Let $d = p_1^{m_1} p_2^{m_2} \dots p_n^{m_n}$ be the decomposition of d into its prime factors $p_1 < p_2 < \dots < p_n$. Write $d_j = p_j^{m_j}$. We may identify the d -dimensional Hilbert space \mathcal{H} with $\mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \dots \otimes \mathcal{H}_n$ where $\mathcal{H}_j = L^2(\mathbb{F}_{d_j})$, \mathbb{F}_{d_j} being the finite field of cardinality d_j . Following the definition in (2.7) construct the unitary operators $W^{(j)}(a_j, x_j)$ when $d = d_j$, $j = 1, 2, \dots, n$ and using Theorem 2.2, the corresponding projections $P^{(j)}(a_j, x_j)$, where $a_j \in \mathbb{F}_{d_j}$, $x_j \in \mathbb{F}_{d_j}$. We now adopt the following convention: for any operator X in $L^2(\mathbb{F}_{d_j}) = \mathcal{H}_j$ denote by the same symbol X the operator in \mathcal{H} defined by $X = X_1 \otimes X_2 \otimes \dots \otimes X_n$ where X_i is the identity operator in \mathcal{H}_i when $i \neq j$ and $X_j = X$. The operator X thus defined in $\mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \dots \otimes \mathcal{H}_n$ is called the *ampliation* of X in \mathcal{H}_j to \mathcal{H} . Since $\mathcal{B}(\mathcal{H})$ can be identified with $\mathcal{B}(\mathcal{H}_1) \otimes \mathcal{B}(\mathcal{H}_2) \otimes \dots \otimes \mathcal{B}(\mathcal{H}_n)$ as Hilbert spaces as well as \star -algebras it follows from Proposition 2.1 that the family

$$\begin{aligned} \mathcal{F} &= \left\{ I, W^{(i_1)}(a_{i_1}, x_{i_1}) W^{(i_2)}(a_{i_2}, x_{i_2}) \dots W^{(i_r)}(a_{i_r}, x_{i_r}), \right. \\ &\quad \left. a_{i_j} \in \mathbb{F}_{d_j}, x_{i_j} \in \mathbb{F}_{d_j} \setminus \{0\}, j = 1, 2, \dots, r, \right. \\ &\quad \left. 1 \leq i_1 < i_2 < \dots < i_r \leq n, r = 1, 2, \dots, n \right\} \end{aligned} \quad (3.1)$$

of unitary operators in \mathcal{H} constitute an orthogonal basis for the operator Hilbert spaces $\mathcal{B}(\mathcal{H})$. Note that the cardinality of \mathcal{F} is, indeed, equal to

$$\begin{aligned} &1 + \sum_{r=1}^n \sum_{1 \leq i_1 < i_2 < \dots < i_r \leq n} (d_{i_1}^2 - 1)(d_{i_2}^2 - 1) \dots (d_{i_r}^2 - 1) \\ &= (1 + d_1^2 - 1)(1 + d_2^2 - 1) \dots (1 + d_n^2 - 1) \\ &= d_1^2 d_2^2 \dots d_n^2 \\ &= d^2, \end{aligned}$$

the dimension of $\mathcal{B}(\mathcal{H})$. For any subset $J = \{i_1, i_2, \dots, i_r\} \subset \{1, 2, \dots, n\}$ where $1 \leq i_1 < i_2 < \dots < i_r \leq n$, define

$$\begin{aligned} d(J) &= d_{i_1} d_{i_2} \dots d_{i_r} \\ d'(J) &= (d_{i_1} + 1)(d_{i_2} + 1) \dots (d_{i_r} + 1), \end{aligned}$$

and for any state ρ in \mathcal{H} , put

$$\begin{aligned} S_\rho(J) &= \sum_{\substack{a_{i_j} \in \overline{\mathbb{F}}_{d_{i_j}}, \\ y_{i_j} \in \mathbb{F}_{d_{i_j}} \forall j}} \left\{ \text{Tr } \rho P^{(i_1)}(a_{i_1}, y_{i_1}) P^{(i_2)}(a_{i_2}, y_{i_2}) \dots P^{(i_r)}(a_{i_r}, y_{i_r}) \right\} \\ &\quad P^{(i_1)}(a_{i_1}, y_{i_1}) P^{(i_2)}(a_{i_2}, y_{i_2}) \dots P^{(i_r)}(a_{i_r}, y_{i_r}) \end{aligned} \quad (3.2)$$

where $\{P^{(i)}(a_i, y_i)\}$ are the one dimensional projections in \mathcal{H}_i determined by the unitary representation $x_i \rightarrow W^{(i)}(a_i, x_i)$ of the additive group \mathbb{F}_{d_i} according to Theorem 2.2 and amplified to the product Hilbert space $\mathcal{H} = \mathcal{H}_1 \otimes \mathcal{H}_2 \otimes \dots \otimes \mathcal{H}_n$. Thus $S_\rho(J)$ is an operator in \mathcal{H} determined by the probabilities $\text{Tr } \rho P^{(i_1)}(a_{i_1}, y_{i_1}) P^{(i_2)}(a_{i_2}, y_{i_2}) \dots P^{(i_r)}(a_{i_r}, y_{i_r})$ and the projections $P^{(i_1)}(a_{i_1}, y_{i_1}) P^{(i_2)}(a_{i_2}, y_{i_2}) \dots P^{(i_r)}(a_{i_r}, y_{i_r})$ of dimension $\prod_{j \notin \{i_1, i_2, \dots, i_r\}} d_j$ with a_i 's varying in $\overline{\mathbb{F}}_{d_i}$ and y_i 's in \mathbb{F}_{d_i} for any i . With these notations and the convention $S_\rho(\emptyset) = I$, we have the following theorem for the recovery of ρ from the probabilities.

Theorem 3.1 Let ρ be any state in \mathcal{H} . Then

$$\rho = \sum_{J \subset \{1, 2, \dots, n\}} (-1)^{n-|J|} S_\rho(J) \quad (3.3)$$

where $S_\rho(J)$ is given by (3.2) and $|J|$ is the cardinality of J .

Proof: Since the family \mathcal{F} of unitary operators in (3.1) is an orthogonal basis for $\mathcal{B}(\mathcal{H})$ we can expand the state ρ in this basis as

$$\begin{aligned} \rho &= (d_1 d_2 \dots d_n)^{-1} \left\{ I + \sum_{r=1}^n \sum_{1 \leq i_1 < i_2 < \dots < i_r \leq n} \sum_{a_{i_j} \in \overline{\mathbb{F}}_{d_{i_j}}, x_{i_j} \in \mathbb{F}_{d_{i_j}} \setminus \{0\}} \right. \\ &\quad \left. \left[\text{Tr } \rho W^{(i_1)}(a_{i_1}, x_{i_1})^\dagger \dots W^{(i_r)}(a_{i_r}, x_{i_r})^\dagger \right] W^{(i_1)}(a_{i_1}, x_{i_1}) \dots W^{(i_r)}(a_{i_r}, x_{i_r}) \right\}. \end{aligned} \quad (3.4)$$

From Theorem 2.2 we have for any fixed i

$$\begin{aligned} &\sum_{x_i \in \mathbb{F}_{d_i} \setminus \{0\}} W^{(i)}(a_i, x_i)^\dagger \otimes W^{(i)}(a_i, x_i) \\ &= \sum_{\substack{y, z \in \mathbb{F}_{d_i} \\ x_i \in \mathbb{F}_{d_i} \setminus \{0\}}} \overline{\langle x_i, y \rangle} \langle x_i, z \rangle P^{(i)}(a_i, y) \otimes P^{(i)}(a_i, z) \\ &= d_i \sum_{y \in \mathbb{F}_{d_i}} P^{(i)}(a_i, y) \otimes P^{(i)}(a_i, y) - I^{(i)} \otimes I^{(i)}, \end{aligned}$$

$I^{(i)}$ being the identity operator in \mathcal{H}_i . Using this identity and elementary properties of relative trace, equation (3.4) can be written as

$$\begin{aligned} \rho &= (d_1 d_2 \dots d_n)^{-1} \sum_J \sum_{K \subset J} (-1)^{|J|-|K|} d(K) d'(J \setminus K) \\ &\times \sum_{\substack{a_{k_i} \in \bar{\mathbb{F}}_{d_{k_i}}, \\ y_{k_i} \in \bar{\mathbb{F}}_{d_{k_i}}^{\forall i}}} \left\{ \text{Tr} \rho P^{(k_1)}(a_{k_1}, y_{k_1}) P^{(k_2)}(a_{k_2}, y_{k_2}) \dots P^{(k_s)}(a_{k_s}, y_{k_s}) \right\} \\ &\times P^{(k_1)}(a_{k_1}, y_{k_1}) P^{(k_2)}(a_{k_2}, y_{k_2}) \dots P^{(k_s)}(a_{k_s}, y_{k_s}) \end{aligned}$$

where J varies over all subsets $i_1 < i_2 < \dots < i_r$ of $\{1, 2, \dots, n\}$ and K varies over all subsets $k_1 < k_2 < \dots < k_s$ of J . Now using the definition in (3.2) we can express ρ as

$$\rho = \sum_{K \subset \{1, 2, \dots, n\}} \alpha(K) S_\rho(K)$$

where

$$\begin{aligned} \alpha(K) &= (d_1 d_2 \dots d_n)^{-1} d(K) \sum_{L: L \cap K = \emptyset} (-1)^{|L|} d'(L) \\ &= (-1)^{n-|K|} \square \end{aligned}$$

Remark From Theorem 3.1 it is clear that ρ is recovered from the probabilities for the elementary events

$$P^{(1)}(a_1, x_1) P^{(2)}(a_2, x_2) \dots P^{(n)}(a_n, x_n), \quad a_i \in \bar{\mathbb{F}}_{d_i}, x_i \in \bar{\mathbb{F}}_{d_i}.$$

In other words the determination of ρ involves $(d_1 + 1)(d_2 + 1) \dots (d_n + 1)$ elementary measurements. As mentioned in the introduction one would like to determine ρ by $d_1 d_2 \dots d_n + 1$ measurements.

Acknowledgement: I wish to thank Professor S. Chaturvedi of the University of Hyderabad for bringing my attention to the central problem of this paper and the reference [7].
